SLE, hydroxychloroquine and no SLE patients with covid-19: a comment

Inter-relationship between covid-19 and rheumatic diseases is an interesting topic in clinical rheumatology. We found that article 'Clinical course of COVID-19 in a series of patients with chronic arthritis treated with immunosuppressive targeted therapies' is informative. Monti et al suggested for 'avoiding the unjustifiable preventive withdrawal of DMARDs, which could lead to an increased risk of relapses and morbidity from the chronic rheumatological condition'.1 Whether standard therapy for rheumatic diseases have any effect on clinical course of covid-19 is an interesting issue. Clinically, co-occurrence between covid-19 and other medical disorder is an interesting situation. We hereby would like to draw attention to a specific disease that is little mentioned, systemic lupus erythematosus (SLE). SLE is a common immunological disorder that is seen worldwide. There are several thousands of patients with covid-19 worldwide. Nevertheless, there is no case of SLE with covid-19. In fact, a similar unusual clinical observation is already mentioned on covid-19 and HIV infection.¹ HIV-infected patients who intake anti-HIV drug might have lower risk to get covid-19 than general population since anti-HIV drug is proven for efficacy against the novel coronavirus.² Regarding SLE, hydroxychloroquine is a widely used drug for treatment.³ Hydroxychloroquine is also reported for efficacy against covid-19.4

Hence, hydroxychloroquine use might be an explanation for no report on SLE patient with covid-19. This is an example that can support the suggestion of Monti *et al* on medication for rheumatic diseases in the present covid-19 crisis.
