Abstract

Background As the pandemic of the novel coronavirus disease 2019 (COVID-19) progresses worldwide, many governments have established phone hotlines to pre-screen potential COVID-19 cases. These hotlines face a deluge of callers which far exceeds their capabilities, thus leading to waiting times of hours or, in many cases, a complete inability to get into contact with health authorities.

Methods Symptoma is a symptom-to-disease digital health assistant that can differentiate more than 20,000 different diseases with an accuracy of more than 90%. We tested the accuracy of Symptoma to identify COVID-19 both with regards to a diverse set of clinical cases and diseases similar in presentation to COVID-19.

Findings We showed that Symptoma can accurately distinguish COVID-19 from diseases with similar symptoms in 96.32% of clinical cases. When considering only COVID-19 symptoms and risk factors, Symptoma identified 100% of those infected when presented with only three symptoms. Lastly, we showed that Symptoma's accuracy exceeds that of simple "yes-no" questionnaires widely available online.

Interpretation Symptoma provides unparalleled accuracy in systematically identifying cases of COVID-19 while concurrently considering over

*Corresponding author

20,000 other diseases. Furthermore, Symptoma offers predefined questions alongside free text input in 36 languages. This makes Symptoma a key tool in taking pressure off from health authorities worldwide. The Symptoma predictor is freely available as a web application at <https://www.symptoma.com>.

Keywords: Science, More Science, Even More Science

1 Introduction

2 Currently, the world is facing an unprecedented health crisis caused by
3 the novel coronavirus disease 2019 (COVID-19). In order to curb this cri-
4 sis, among many other measures, large-scale COVID-19 laboratory testing is
5 carried out. However, capacities are far from being able to test whole popula-
6 tions. Therefore many countries have established phone hotlines to pre-screen
7 persons who are unsure about their COVID-19 infection status. Only after
8 talking to an operator and being identified as a potential case will labora-
9 tory testing occur. However, these hotlines are severely overrun worldwide,
10 leading to hour-long waiting periods and disconnected lines, which leads to
11 many COVID-19 cases going undiagnosed.

12 Here computer-based approaches can step in. Approaches can be grouped
13 into two categories. Firstly, a large number of simple yes/no online question-
14 naires are available. These questionnaires lead straight to the point but are
15 limited in their informative value as they do not provide a deeper under-
16 standing of a patient's health situation, do not allow for the consideration
17 of additional symptoms, do not allow the generation of additional data for
18 analysis, and are often language- and country-specific. Secondly, there are
19 several general-purpose symptom checkers available that have already been
20 developed over several years (benchmarked in Nateqi et al. [1]). However,
21 most of these symptom checkers are highly restricted in the number of dis-
22 eases taken into account as building up the database is quite cost-intensive,
23 slow, and language ambiguities are hard to overcome leading to small dis-
24 ease databases and users can only choose from a limited list of pre-defined
25 symptoms which makes those tools not viable. We have also recently shown
26 that our Symptoma engine outperforms other symptom checkers by a large
27 margin [1]. This was also confirmed by another study [2]. In the following,
28 we present COVID-19 specific Symptoma version that allows for predictions
29 and analysis way beyond currently available methods.

30 **2. Methods**

31 *2.1. Test cases*

32 In order to show the performance of Symptoma for COVID-19 we anal-
33 ysed a total of 1,142 medical test cases. The different sets and sources of
34 these cases are described below.

35 *2.1.1. BMJ Cases*

36 A total of 1,112 cases were sourced from the British Medical Journal
37 (BMJ) [3, 4] and transcribed by a medical clinician into sets of symptoms,
38 both negative and positive, alongside other risk factors, the patient’s age
39 and sex when available. The cases cover a hugely diverse range of causes,
40 including but not limited to rib fractures, rabies, or metastatic cancer. The
41 number of symptoms and keywords per case ranges from one to 33 (median
42 eight) including terms like “right true vocal cord is immobile” and “metal
43 buttons”.

44 *2.1.2. Covid-19 Cases*

45 A set of 30 case reports were derived from the current literature (e.g. [5,
46 6, 7, 8]). For each case, a list of symptoms and risk factors the patient is
47 presented with is given alongside age and sex.

48 *2.1.3. COVID-19 - computer generated*

49 We make use of the World Health Organisation (WHO) COVID-19 symp-
50 tom list to construct example queries from those infected with COVID-19
51 [9]. The ten most frequent symptoms are combined with both “contact with
52 someone infected with COVID-19” and “visiting/living in a COVID-19 risk
53 area”, to give 12 possible symptoms and/or risk factors. All possible combi-
54 nations of these are then taken as potential COVID-19 cases yielding a total
55 number of 4096 artificial cases.

56 *2.2. Accuracy Measurements*

57 For any given set of symptoms, many possible causes could give rise to
58 that specific presentation. We count a prediction as true positive if the true
59 cause is listed within the top 30 results returned by Symptoma. With respect
60 to the possible 20,000 causes within Symptoma this is the top 0.15%.

61 Focussing on COVID-19, we can generate the following classification:

- 62 • True positive: C19 case and C19 returned in top 30 results

- 63 • False positive: Non-C19 case and C19 returned in top 30 results
- 64 • True negative: Non-C19 case and C19 not returned in top 30 results
- 65 • False negative: C19 case and C19 not returned in top 30 results

66 3. Results

67 3.1. Sensitivity and specificity

68 Symptoma classifies nearly all 30 COVID-19 case descriptions correctly as
69 COVID-19 cases (96.6% sensitivity), failing only when presented with a case
70 containing no defining symptoms of COVID-19 (Fever, Fatigue, Dizziness,
71 Constipation, Rhonchi, Tachypnea, and Bilateral pneumonia). Achieving
72 100% sensitivity is however easy e.g. by constructing a test that simply clas-
73 sifies every case as COVID-19. To address this issue we also tested how well
74 Symptoma performs on cases of non-COVID-19 patients. For this purpose
75 we use the above described 1,112 BMJ cases that stretch over 84 fields of
76 medicine. Of these 1,112 cases, only 41 are classified as potential COVID-19
77 cases by Symptoma, with only seven of these ranking COVID-19 higher than
78 the correct diagnoses. These seven cases relate to diseases that present sim-
79 ilarly to COVID-19, however, have far lower incidence rates and, therefore,
80 are deemed less likely, e.g., Severe Acute Respiratory Syndrome (SARS-CoV)
81 or the Avian influenza A (H5N1) virus infection (bird flu). The results are
82 summarized in Table 1.

	n cases	Flagged as COVID-19 Risk	Not flagged as COVID-19 Risk
COVID-19 cases	30	29 (TP)	1 (FN)
BMJ cases	1112	41 (FP)	1071 (TN)
Sensitivity	96.66% (29 of 30 detected)		
Specificity	96.31% (1071 of 1112 not wrongly detected)		
Accuracy	96.32% (1158 of 1166 predictions correct)		

Table 1: Sensitivity and specificity of Symptoma in COVID-19 cases and BMJ negative controls.

83 3.2. *Discovery speed and sensitivity*

84 Identifying patients presenting with COVID-19 both quickly and effi-
85 ciently is of utmost importance to digital diagnoses. However, achieving
86 both speed and accuracy simultaneously is remarkably difficult. Short, and
87 therefore quick, questionnaires will typically have low specificity, while con-
88 versely, long questionnaires lack efficiency and speed, often containing many
89 questions not pertinent to any given patient. Symptoma’s free text search al-
90 lows quick, efficient, and complex queries of symptom’s without constraint to
91 a predefined list of symptoms. To highlight this with regards to COVID-19,
92 we show in Figure 1, the search rank of queries containing various numbers of
93 symptoms known to be present in those infected with COVID-19 (see Meth-
94 ods). Key symptoms, such as suffering a fever or living in an area with a
95 high incidence of COVID-19, leads to COVID-19 suggested within the top
96 30 search results immediately. This threshold is passed by 75%, 98.5%, and
97 100% of one, two, and three symptom queries respectively. At three symp-
98 toms, 99.1% of the possible combinations are returned within the top 10
99 results, and with four symptoms, all queries return COVID-19 within the
100 top 10. These results highlight the speed with which a correct diagnosis can
101 be observed, even when minimal symptoms are entered into the query.

102 Please note that the Symptoma web application gives immediate feedback
103 to the user after each added symptom and/or answered question thereby
104 making use of a slight gamification approach. Therefore quick convergence
105 is important and this is shown by the above analysis.

106 3.3. *Symptoma performs better than simple approaches*

107 Next we show how well Symptoma performs in comparison to relatively
108 simple COVID-19 symptom checkers. These symptom checkers aim to deter-
109 mine (given a limited set of symptoms as input) the likelihood of suffering
110 from COVID-19 in comparison to influenza, common cold or hay fever. These
111 symptom checkers are based on literature derived symptom frequencies (see
112 Table S1) for each disease. For this purpose we have implemented four dif-
113 ferent methods: vector calculus based distance in space between case presen-
114 tation and symptom frequency (SF-DIST), distance normalised by the stan-
115 dard deviation (=z-score) (SF-SD), distance based on principal component
116 analysis (PCA)(SF-PCA) and cosine similarity (SF-COS) (these methods are
117 described in more detail in the SI).

118 To evaluate the performance of these approaches in comparison to Symp-
119 toma, we classified the combined COVID-19 and BMJ cases of Table 1

Figure 1: Identification of COVID-19 cases with regards to number of query terms entered. On the x-axis the search rank of the query in Symptoma against the y-axis, where each panel considers a different number of symptoms in the query. Only reported COVID-19 symptoms are considered. Points are jittered vertically for clarity only.

120 that have at least one COVID-19 symptom ($n=394$) with all four simple
121 approaches. A case is classified as COVID-19-positiv if the probability of
122 COVID-19 is at least 5% higher than the probability for influenza, common
123 cold or hay fever. As Symptoma weights COVID-19 against more than 20.000
124 diseases we use the definition as stated within the Methods.

125 The results are summarised in Figure 2. It can be seen that Symptoma
126 performs considerably better than any of the more simplistic approaches.
127 This is surprising as the simple approaches just take COVID-19, common
128 cold, flu, and hay fever into account which gives them the significant advan-
129 tage of a 25% chance of a random guess to be correct.

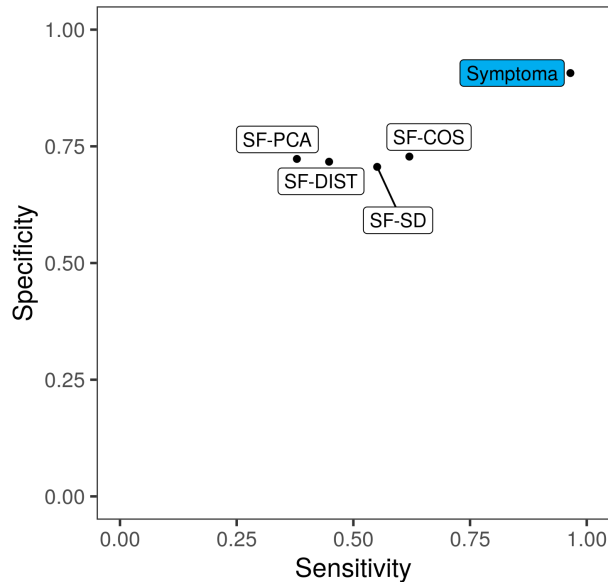

Figure 2: Comparison between four simple approaches and Symptoma using a scatter plot of sensitivity and specificity.

130 3.4. Free text input

131 A major limitation of other COVID-19 questionnaires and symptom check-
132 ers is that patients can only select from a predefined list of symptoms and
133 answer fixed questions. Symptoma allows the patient to enter any type of
134 symptom and the input is semantically understood. For example the symp-
135 tom “Tiramisu” leads to the diagnosis “Salmonella Food Poisoning”, “Pizza”
136 and “Spaghetti” lead to “Overeating”, “Donald Trump” to “Brachydactyly
137 of Fingers” (short fingers) and “Fever” and “Italy” to “COVID-19”. Please
138 note that these are not hard-coded within Symptoma but a result of the
139 Symptoma AI that automatically associates the meaning of symptoms with
140 more than 20,000 diseases.

141 This free text input allows us to analyse if persons with a high risk of
142 COVID-19 also have additional symptoms like the recently discovered anos-
143 mia [10, 11].

144 3.5. Availability in 36 languages

145 Symptoma is currently available in 36 languages aiming for ≥ 100 by the
146 end of 2020. Due to standardization we overcome the language barrier and

147 symptom-to-disease-predictions established from e.g. English scientific pub-
148 lications are also available in languages with fewer scientific publications.
149 Vice versa the multi-language approach allows us to collect and analyse data
150 from many countries around the world and provide a global view on entered
151 symptoms and disease distributions.

152 *3.6. Discussion*

153 We present the application of the symptom-to-disease search engine Symp-
154 toma to COVID-19 cases and BMJ-derived decoy cases. Our methodology is
155 superior to alternative approaches in multiple aspects. First, to the best of
156 our knowledge there is no symptom-to-disease predictor that allows free text
157 input that is semantically understood. Second, we are able to weigh COVID-
158 19 not only against a few diseases but against more than 20,000 differential
159 diagnoses which is far beyond the largest number of differential diagnoses
160 by the second largest tool Isabel Healthcare with about 6,000 differential
161 diagnoses [12]. Third, our predictive method is far beyond simplistic and
162 pre-defined “if-then” or tree-like approaches. By constantly mining the cur-
163 rent literature our system is up-to-date with the latest knowledge in almost
164 real-time. Fourth, in contrast to other solutions Symptoma is available in 36
165 languages allowing a centralised approach on disease predictions and allow-
166 ing standardised triage efforts. On these grounds we believe that Symptoma
167 is a highly valuable tool in the global COVID-19 crisis.

214 **Appendix A. Detailed methods of the simple predictors**

215 We developed four different methods to weight the probability of a patient
216 having COVID-19, influenza, common cold or hay fever. For this purpose
217 we collected symptom frequencies for these four diseases from the literature
218 (Table A.2). To determine the probability of each of the four diseases we
219 represent each patient case as a 10-dimensional point where each dimension
220 is either 1 (has the symptom), 0 (does not have the symptom), or 0.5 (does
221 not know / unknown).

222 In the most simplistic approach (SF-DIST) we just calculate the distance
223 in space between the patient and each of the four diseases (that can also be
224 seen as 10-dimensional points). Normalisation yields the respective proba-
225 bilities. In the second approach the same procedure is used but the distance
226 in space is normalised by the standard deviation (=z-score) (SF-SD). In the
227 third approach the influence of each symptom frequency is weighted by a
228 PCA on all frequencies (SF-PCA). In the fourth approach we interpret the
229 points as vectors and use the cosine similarity between them instead of the
230 distance (SF-COS).

	COVID-19	Common cold	Influenza	Hay fever
Fever	87.9 [1]	15 [3]	68 [6]	NR
Fatigue	38.1 [1]	42 [4]	94 [6]	NR
Dry cough	67.7 [1]	80 [3]	93 [6]	22 [10]
Sneezing	NR	74 [4]	58 [7]	96 [11]
Malaise	14.8 [1]	30 [4]	94 [6]	NR
Rhinorrhea	4 [2]	95 [3]	91 [6]	62.1 [12]
Sore throat	13.9 [1]	70 [3]	84 [6]	30 [10]
Diarrhea	3.7 [1]	11 [4]	14.4 [8]	NR
Headache	13.6 [1]	80 [5]	91 [6]	50 [13]
Dyspnea	18.6 [1]	21 [4]	63 [9]	NR
